Common Types of Conceptual Physics Exercises in Chapter 24

Exercises in this chapter often challenge students to analyze scenarios involving wave behavior, calculate wave parameters, and explain phenomena related to sound and waves.

Key exercise categories include:

- Wave Properties and Calculations
- Sound Wave Behavior and Characteristics
- Wave Interference and Standing Waves

- Doppler Effect
- Resonance and Applications

Detailed Answers to Conceptual Physics Exercises in Chapter 24

Below, we explore typical exercises with detailed, step-by-step answers to help you understand the concepts thoroughly.

1. Wave Properties and Calculations

Exercise 1: A wave on a string has a frequency of 10 Hz and a wavelength of 2 meters. What is the speed of the wave?

Answer:

Using the wave speed formula:

$$v = f \times \lambda$$

Where:

- v = wave speed
- f = frequency = 10 Hz
- λ = wavelength = 2 m

Calculation:

$$v = 10 \, \text{Hz} \times 2 \, \text{m} = 20 \, \text{m/s}$$

Therefore, the wave speed is 20 meters per second.

Exercise 2: If a sound wave travels at 340 m/s in air and has a wavelength of 0.68 meters, what is its frequency?

Answer:

Using the same wave equation:

$$f = \frac{v}{\lambda}$$

Calculation:

$$f = \frac{340 \text{ m/s}}{0.68 \text{ m}} \approx 500 \text{ Hz}$$

The frequency of the sound wave is approximately 500 Hz.

2. Sound Wave Behavior and Characteristics

Exercise 3: Explain why sound travels faster in water than in air.

Answer:

Sound travels faster in water than in air primarily because water molecules are more tightly packed and interact more strongly than air molecules. The increased density and elastic properties of water allow sound waves to propagate more quickly. Specifically:

- Density: Water is denser, providing a medium that transmits vibrations more efficiently.
- Elasticity: Water's elastic properties are higher, meaning it can restore its shape after deformation more effectively.

As a result, the speed of sound in water (~1482 m/s) exceeds that in air (~343 m/s at room temperature).

Exercise 4: Describe how the amplitude of a sound wave affects its loudness.

Answer:

The amplitude of a sound wave correlates directly with its loudness. Larger amplitudes mean greater energy in the wave, resulting in louder sounds that are perceived as more intense. Conversely, smaller amplitudes produce softer sounds. This relationship is subjective but generally accepted: as amplitude increases, loudness increases proportionally to the square root of the energy.

3. Wave Interference and Standing Waves

Exercise 5: What is the difference between constructive and destructive interference?

Answer:

- Constructive interference occurs when two waves meet in phase, meaning their crests and

troughs align. The result is a wave with greater amplitude, leading to a louder or more intense wave.

- Destructive interference occurs when two waves meet out of phase, with crests aligning with troughs. This causes the waves to cancel each other out partially or completely, resulting in reduced amplitude or silence.

In summary:

- Constructive interference amplifies wave effects.
- Destructive interference diminishes or cancels wave effects.

Exercise 6: In a string fixed at both ends, standing waves form at specific frequencies. What determines these frequencies?

Answer:

Standing wave frequencies are determined by the length of the string, the wave speed, and the boundary conditions. The fundamental frequency (first harmonic) occurs when the string vibrates with a single antinode in the middle, and higher harmonics are integer multiples of this frequency.

The formula for the n th harmonic:

$$f_n = n \times \frac{v}{2L}$$

Where:

- n = harmonic number (1, 2, 3, ...)
- v = wave speed in the string
- L = length of the string

Thus, the specific frequencies at which standing waves form are quantized and depend on these parameters.

4. Doppler Effect

Exercise 7: A police siren emits a sound at a frequency of 1000 Hz. If the police car approaches an observer at 30 m/s and the speed of sound is 340 m/s, what frequency does the observer perceive?

Answer:

Using the Doppler effect formula for a moving source approaching a stationary observer:

$$f' = f \times \frac{v + v_o}{v}$$

Where:

- f' = perceived frequency
- f = emitted frequency = 1000 Hz
- v = speed of sound = 340 m/s
- v_o = velocity of source toward the observer = 30 m/s

Calculation:

$$f' = 1000 \text{ Hz} \times \frac{340 \text{ m/s} + 30 \text{ m/s}}{340 \text{ m/s}} = 1000 \text{ Hz} \times \frac{370}{340} \approx 1000 \times 1.088 = 1088 \text{ Hz}$$

The observer perceives the sound at approximately 1088 Hz.

Exercise 8: If the same source moves away from the observer at 30 m/s, what is the perceived frequency?

Answer:

For a source moving away:

$$f' = f \times \frac{v}{v + v_o}$$

Calculation:

$$f' = 1000 \text{ Hz} \times \frac{340}{340 + 30} = 1000 \times \frac{340}{370} \approx 1000 \times 0.919 = 919 \text{ Hz}$$

The observer perceives the sound at approximately 919 Hz.

5. Resonance and Applications

Exercise 9: Describe how resonance can cause a glass to break when exposed to a certain sound frequency.

Answer:

Resonance occurs when an external sound wave matches the natural frequency of an object, causing it to vibrate with increasing amplitude. If the sound's amplitude is sufficiently high and the frequency precisely matches the object's natural frequency, the vibrations can become intense enough to weaken or break the object.

In the case of a glass:

- When exposed to a sound at its natural frequency, the glass vibrates vigorously.
- These vibrations can exceed the material's structural limits.
- The resulting stress causes the glass to shatter.

This principle is exploited in musical performances and demonstrates the importance of matching frequencies in resonance phenomena.

Exercise 10: How do engineers utilize standing waves and resonance in designing musical instruments?

Answer:

Engineers and instrument makers exploit resonance and standing waves to produce specific notes:

- String instruments: Strings are tuned so that their length and tension produce standing waves at desired frequencies.
- Wind instruments: The length of air columns is adjusted to resonate at particular frequencies, producing specific pitches.
- Resonance chambers: These amplify sound by creating standing waves, enhancing volume and tonal quality.

By controlling these parameters, designers craft instruments that produce clear, stable notes with desired tonal characteristics.

Additional Tips for Success with Chapter 24 Exercises

Ch 24 Conceptual Physics Exercises Answers: An In-Depth Review and Guide

Understanding Chapter 24 of Conceptual Physics can be challenging for students, especially when it comes to mastering the exercise questions and their solutions. This chapter often delves into complex topics such as electromagnetic induction, electric circuits, and magnetic fields, requiring a thorough grasp of fundamental concepts. In this comprehensive review, we will explore the key themes, typical exercises, and their detailed answers, providing clarity and confidence for students seeking mastery over this material.

Overview of Chapter 24: Core Concepts and Themes

Before diving into specific exercises and their answers, it's essential to understand the overarching themes of Chapter 24. This chapter primarily focuses on electromagnetism, including the principles governing electric currents, magnetic fields, and electromagnetic induction.

Key Concepts Covered:

- Electromagnetic Induction: How changing magnetic flux induces an electric current.
- Faraday's Law: Quantitative relation between the rate of change of magnetic flux and induced emf.
- Lenz's Law: The direction of induced current opposes the change causing it.
- Transformers: Devices that transfer electrical energy between circuits through electromagnetic induction.
- Electric Circuits: Series and parallel configurations, resistance, and voltage/current relationships.
- Magnetic Fields: How currents produce magnetic fields, and the forces they exert.

Why Mastering Exercise Answers Matters:

- Reinforces theoretical understanding.
- Develops problem-solving skills.
- Prepares students for exams and practical applications.
- Clarifies misconceptions through detailed explanations.

Common Types of Exercises and Their Solutions

Chapter 24 exercises typically include conceptual questions, quantitative problems involving calculations, and real-world application scenarios. Below, we explore representative examples with detailed solutions.

1. Understanding Electromagnetic Induction

Question:

What causes an emf to be induced in a coil of wire? Describe the process in terms of magnetic flux.

Answer:

An emf is induced in a coil of wire when there is a change in the magnetic flux passing through it. Magnetic flux (Φ) is defined as:

[

$$\Phi = B \times A \times \cos \theta$$

]

where:

- B is the magnetic field strength,
- A is the area of the coil,
- θ is the angle between the magnetic field and the normal to the coil.

Process:

- When the magnetic field B varies over time (either by changing the field strength, moving the coil, or changing the orientation), the magnetic flux Φ also changes.
- According to Faraday's Law:

[

$$\text{Induced emf } (\varepsilon) = - \frac{d\Phi}{dt}$$

\]

- The negative sign indicates Lenz's law, meaning the induced emf opposes the change in flux.

Key Point:

Any change in magnetic flux—whether through movement of the coil, variation in (B) , or rotation—induces an emf, leading to a current if the circuit is closed.

2. Applying Faraday's Law

Question:

A coil with an area of 0.5 m^2 experiences a change in magnetic flux from 0.3 Wb to 0.1 Wb in 0.2 seconds. What is the magnitude of the induced emf?

Answer:

Given data:

- Initial flux, $(\Phi_i = 0.3, \text{Wb})$
- Final flux, $(\Phi_f = 0.1, \text{Wb})$
- Time interval, $(\Delta t = 0.2, \text{s})$

Calculate change in flux:

\[

$$\Delta \Phi = \Phi_f - \Phi_i = 0.1 - 0.3 = -0.2, \text{Wb}$$

\]

Using Faraday's Law:

\[

$$\epsilon = - \frac{\Delta \Phi}{\Delta t} = - \frac{-0.2}{0.2} = 1, \text{V}$$

\]

Interpretation:

The magnitude of the induced emf is 1 volt. The negative sign in the calculation aligns with Lenz's law, indicating the induced current opposes the change in flux.

3. Magnetic Force on a Moving Charge

Question:

Calculate the magnetic force on a proton moving at $(3 \times 10^6 \text{ m/s})$ perpendicular to a magnetic field of 0.5 T.

Answer:

The magnetic force on a moving charge is given by:

$$F = q v B \sin \theta$$

$$F = q v B \sin \theta$$

$$F = q v B \sin \theta$$

where:

- $(q = 1.6 \times 10^{-19} \text{ C})$ (charge of proton),
- $(v = 3 \times 10^6 \text{ m/s})$,
- $(B = 0.5 \text{ T})$,
- $(\theta = 90^\circ)$ (perpendicular motion), so $(\sin \theta = 1)$.

Calculating:

$$F = q v B \sin \theta$$

$$F = (1.6 \times 10^{-19}) \times (3 \times 10^6) \times 0.5 = 2.4 \times 10^{-13} \text{ N}$$

$$F = q v B \sin \theta$$

Conclusion:

The magnetic force acting on the proton is (2.4×10^{-13}) Newtons, directed perpendicular to

both the velocity and magnetic field.

4. Transformers and Energy Transfer

Question:

In a transformer with 200 turns in the primary coil and 50 turns in the secondary coil, if the primary voltage is 120 V, what is the secondary voltage?

Answer:

Transformers operate on the principle:

$\left[$

$$\frac{V_s}{V_p} = \frac{N_s}{N_p}$$

$\left]$

where:

- $(V_p = 120\text{ V})$,
- $(N_p = 200)$,
- $(N_s = 50)$,
- $(V_s = ?)$

Calculating:

$\left[$

$$V_s = V_p \times \frac{N_s}{N_p} = 120 \times \frac{50}{200} = 120 \times 0.25 = 30\text{ V}$$

$\left]$

Understanding:

This is a step-down transformer reducing voltage from 120 V to 30 V. The current in the secondary increases proportionally, assuming ideal conditions.
