Algebra and Functions

Sample Question:

Given the quadratic function $f(x) = 2x^2 - 4x + 1$, find its vertex, axis of symmetry, and the maximum or minimum value.

Solution:

- Identify coefficients:

$$(a=2), (b=-4), (c=1)$$

- Vertex:

The x-coordinate of the vertex is given by $(-\frac{b}{2a})$:

[

$$x_v = -\frac{-4}{2 \times 2} = \frac{4}{4} = 1$$

]

- Calculate the y-coordinate:

[

$$f(1) = 2(1)^2 - 4(1) + 1 = 2 - 4 + 1 = -1$$

]

- Vertex point:

$$\backslash(1, -1)\backslash$$

- Axis of symmetry:

The vertical line passing through the vertex:

$$\backslash[$$

$$x = 1$$

$$\backslash]$$

- Nature of the vertex:

Since $\backslash(a=2 > 0)\backslash$, the parabola opens upward, so the vertex represents a minimum point.

Answer Summary:

- Vertex: $\backslash(1, -1)\backslash$
- Axis of symmetry: $\backslash(x=1)\backslash$
- Minimum value: $\backslash(-1)\backslash$

Calculus: Differentiation

Sample Question:

Find the maximum value of $\backslash(g(x) = -3x^3 + 6x^2 + 2)\backslash$ on the interval $\backslash([0, 3])\backslash$.

Solution:

- Find critical points:

Differentiate $\backslash(g(x))\backslash$:

$$\backslash[$$

$$g'(x) = -9x^2 + 12x$$

\]

- Set derivative to zero:

\[

$$-9x^2 + 12x = 0 \Rightarrow x(-9x + 12) = 0$$

\]

- Solve for x :

\[

$$x=0 \quad \text{or} \quad -9x + 12=0 \Rightarrow x = \frac{12}{9} = \frac{4}{3}$$

\]

- Evaluate $g(x)$ at critical points and endpoints:

| x | $g(x)$ calculation | $g(x)$ value |

|---|---|---|

| 0 | $-3(0)^3 + 6(0)^2 + 2$ | 2 |

| $\frac{4}{3}$ | $-3 \times (\frac{4}{3})^3 + 6 \times (\frac{4}{3})^2 + 2$ | $-3 \times \frac{64}{27} + 6 \times \frac{16}{9} + 2$ |

Calculations:

\[

$$-3 \times \frac{64}{27} = -\frac{192}{27} = -\frac{64}{9}$$

\]

[

$$6 \times \frac{16}{9} = \frac{96}{9} = \frac{32}{3}$$

]

Adding all:

[

$$g(4/3) = -\frac{64}{9} + \frac{32}{3} + 2$$

]

Express all with denominator 9:

[

$$-\frac{64}{9} + \frac{96}{9} + \frac{18}{9} = \frac{-64 + 96 + 18}{9} = \frac{50}{9} \approx 5.56$$

]

- Determine maximum:

| Point | $g(x)$ value |

|---|---|

| 0 | 2 |

| $4/3$ | ≈ 5.56 |

| 3 | $-3(27) + 6(9) + 2 = -81 + 54 + 2 = -25$ |

Conclusion:

The maximum value on $[0, 3]$ is approximately 5.56 at $(x = \frac{4}{3})$.

In 2003, curricula across universities in many countries emphasized both theoretical understanding and practical problem-solving skills. The course would have aimed to equip students with the ability to rigorously analyze mathematical problems, apply theoretical concepts to real-world scenarios, and develop proofs or computational solutions.

Examination Format and Significance

The November 2003 assessment?possibly a final exam or a mid-term?served as a crucial indicator of student mastery. These exams typically consist of a mixture of question types:

- Short answer and computational problems
- Proof-based questions
- Application-oriented problems

The answers to these questions provide a window into the pedagogical priorities of the time, reflecting a focus on both conceptual understanding and technical proficiency.

Structure and Content of the November 2003 Assessment

Common Topics Covered

Based on the course title and typical curriculum structure, the November 2003 exam likely addressed several core areas:

- Real Analysis: limits, continuity, differentiation, integration
- Linear Algebra: vector spaces, eigenvalues, matrix transformations
- Differential Equations: solutions methods, stability analysis
- Mathematical Modeling: applying mathematical concepts to real-world problems
- Probability and Statistics (depending on the course scope)

The exam questions would be designed to test both theoretical knowledge and problem-solving skills within these domains.

Question Types and Their Purposes

The exam probably included:

- Definition and theorem-based questions: testing understanding of fundamental concepts
- Proof questions: requiring rigorous mathematical reasoning
- Computational problems: involving calculations, derivations, or algorithmic solutions
- Application problems: applying theories to new scenarios or data sets

Analyzing the Typical Questions and Their Solutions

Sample Question 1: Limit and Continuity

Question:

Evaluate the limit $\lim_{x \rightarrow 0} \frac{\sin 3x}{x}$ and determine whether the function $f(x) =$

$\frac{\sin 3x}{x}$ is continuous at $(x = 0)$.

Answer Analysis:

The limit can be approached using standard limit properties and known limits involving sine functions:

[

$$\lim_{x \rightarrow 0} \frac{\sin 3x}{x} = \lim_{x \rightarrow 0} 3 \frac{\sin 3x}{3x} = 3 \times 1 = 3.$$

]

Since $f(x)$ is not defined at $(x=0)$, we define $f(0) = 3$ to make it continuous at that point.

This question tests understanding of limits involving trigonometric functions, the application of the standard limit $(\lim_{x \rightarrow 0} \frac{\sin x}{x} = 1)$, and the concept of continuity.

Sample Question 2: Eigenvalues and Eigenvectors

Question:

Find the eigenvalues and eigenvectors of the matrix

[

$$A = \begin{bmatrix} 4 & 1 \\ 2 & 3 \end{bmatrix}.$$

]

Answer Analysis:

Eigenvalues are found by solving the characteristic equation:

[

$$\det(A - \lambda I) = 0,$$

]

which yields:

$\begin{vmatrix}$

$$\det \begin{bmatrix} 4 - \lambda & 1 \\ 2 & 3 - \lambda \end{bmatrix} = (4 - \lambda)(3 - \lambda) - 2 \times 1 = 0.$$

$\end{vmatrix}$

Expanding:

$\begin{vmatrix}$

$$(4 - \lambda)(3 - \lambda) - 2 = (12 - 4\lambda - 3\lambda + \lambda^2) - 2 = \lambda^2 - 7\lambda + 10 = 0.$$

$\end{vmatrix}$

Solving the quadratic:

$\begin{vmatrix}$

$$\lambda^2 - 7\lambda + 10 = 0,$$

$\end{vmatrix}$

gives:

$\begin{vmatrix}$

$$\lambda = \frac{7 \pm \sqrt{49 - 40}}{2} = \frac{7 \pm 3}{2},$$

$\end{vmatrix}$

so:

- $(\lambda_1 = 5)$,
- $(\lambda_2 = 2)$.

Eigenvectors are found by solving $((A - \lambda I)\mathbf{v} = 0)$ for each eigenvalue.

For $(\lambda=5)$:

$$\begin{bmatrix}$$

$$\begin{bmatrix} -1 & 1 \\ 2 & -2 \end{bmatrix} \mathbf{v} = 0,$$

$$\end{bmatrix}$$

which simplifies to:

$$\begin{bmatrix}$$

$$-1 v_1 + v_2 = 0 \Rightarrow v_2 = v_1,$$

$$\end{bmatrix}$$

so an eigenvector is any scalar multiple of $\begin{bmatrix} 1 \\ 1 \end{bmatrix}$.

Similarly for $(\lambda=2)$:

$$\begin{bmatrix}$$

$$\begin{bmatrix} 2 & 1 \\ 2 & 1 \end{bmatrix} \mathbf{v} = 0,$$

$$\end{bmatrix}$$

which reduces to:

$$\begin{bmatrix}$$

$$2 v_1 + v_2 = 0 \Rightarrow v_2 = -2 v_1,$$

$$\end{bmatrix}$$

and an eigenvector is any scalar multiple of $\begin{bmatrix} 1 \\ -2 \end{bmatrix}$.

This problem demonstrates eigenvalue computation and the significance of eigenvectors in linear algebra.
