Root-Finding Methods

Finding roots of nonlinear equations is a foundational problem in engineering analysis.

- Bisection Method:

A bracketing technique that repeatedly halves an interval containing a root until the desired accuracy is achieved.

Process:

- Identify initial interval $[a, b]$ where $f(a)$ and $f(b)$ have opposite signs.
- Compute midpoint $c = (a + b)/2$.
- Determine the subinterval $[a, c]$ or $[c, b]$ where the sign change occurs.
- Repeat until the function value at c is sufficiently close to zero.

- False Position (Regula Falsi):

Uses a linear approximation to estimate the root, often converging faster than bisection.

- Newton-Raphson Method:

An iterative approach that uses tangents to approximate roots, requiring derivatives.

Formula:

$$x_{n+1} = x_n - f(x_n)/f'(x_n)$$

- Secant Method:

Similar to Newton-Raphson but approximates derivatives numerically, eliminating the need for derivative calculations.

Numerical Differentiation and Integration

- Finite Difference Approximations:

Methods to estimate derivatives based on function values at discrete points, crucial for solving differential equations.

- Numerical Integration Techniques:

- Trapezoidal Rule: Approximates the area under a curve using trapezoids.
