Common Questions and Solutions in Physics Unit VII Test V1

Below we examine some typical questions from Physics Unit VII tests and provide detailed answers and explanations.

Question 1: Describe the Properties of Mechanical Waves

Sample Question:

What are the main properties of mechanical waves, and how do they differ from electromagnetic waves?

Answer:

Mechanical waves are disturbances that propagate through a medium (solid, liquid, or gas). Their main properties include:

- Wavelength (λ): The distance between successive crests or troughs.
- Frequency (f): Number of wave cycles passing a point per second.
- Amplitude: The maximum displacement from the rest position.
- Wave Speed (v): How fast the wave travels through the medium, given by $v = f\lambda$.
- Speed depends on the medium's properties: Density and elasticity influence wave speed.

Differences from Electromagnetic Waves:

- Mechanical waves require a medium to travel (e.g., air, water).
- Electromagnetic waves (light, radio waves) can travel through a vacuum.
- Mechanical waves include sound and seismic waves, while electromagnetic waves include visible light, X-rays, and radio waves.

Question 2: Explain the Doppler Effect and Provide an Example

Sample Question:

What is the Doppler effect, and how does it affect the frequency of sound waves?

Answer:

The Doppler effect refers to the change in frequency (and wavelength) of a wave as observed by an observer moving relative to the source of the wave.

- When the source and observer move closer: The observed frequency increases (higher pitch in sound).
- When they move apart: The observed frequency decreases (lower pitch).

Example:

A siren on an ambulance approaches you; the pitch sounds higher as it approaches and lower as it moves away. This change is due to the Doppler effect.

Mathematically:

$$f' = f (v \pm v_o) / (v \mp v_s)$$

Where:

- f' = observed frequency
- f = emitted frequency
- v = speed of sound in the medium
- v_o = speed of the observer (positive if moving towards the source)
- v_s = speed of the source (positive if moving away from the observer)

Question 3: Describe the Laws of Reflection and Refraction

Sample Question:

What are the laws of reflection and refraction? Provide examples illustrating each.

Answer:

Laws of Reflection:

- The angle of incidence (θ_i) equals the angle of reflection (θ_r).
- The incident ray, reflected ray, and the normal to the surface all lie in the same plane.

Example:

Light hitting a mirror reflects at the same angle it arrives, enabling images to form.

Laws of Refraction:

- The incident ray, refracted ray, and the normal all lie in the same plane.
- The ratio of the sine of the angle of incidence (θ_i) to the sine of the angle of refraction (θ_r) is constant, given by Snell's Law:

$$n_i \sin \theta_i = n_r \sin \theta_r$$

where n_i and n_r are the refractive indices of the media.

Example:

A straw appearing bent in a glass of water is due to refraction, where light changes speed as it passes from air to water.

- v_s = source velocity (positive if moving away from observer)

Sample Questions and Corresponding Answer Key Explanations

Question 1:

A stationary observer detects a sound from a source moving towards them at 25 m/s. The wave speed is 340 m/s, and the emitted frequency is 1000 Hz. What is the observed frequency?

Answer:

Using the Doppler formula with the observer stationary ($v_o = 0$) and source moving towards the observer ($v_s = -25$) m/s:

\\

$$f' = \frac{f v}{v - v_s} = \frac{1000 \times 340}{340 - (-25)} = \frac{340,000}{365} \approx 931.5, \text{ Hz}$$

\\

Question 2:

A source emits sound at 600 Hz. An observer moves away from the source at 30 m/s, with wave speed at 340 m/s. What is the observed frequency?

Answer:

Since the observer moves away ($v_o = +30$) m/s and source is stationary ($v_s = 0$):

$$f' = \frac{f (v + v_o)}{v} = \frac{600 \times (340 + 30)}{340} = \frac{600 \times 370}{340} \approx 652.9 \text{ Hz}$$

Common Doppler Shift Problems and Gizmo Answers

Below are typical problems encountered when working with Doppler shift gizmos, along with detailed solutions.

Problem 1: Moving Source Approaching a Stationary Observer

Scenario: A source emits sound at a frequency of 500 Hz and moves toward a stationary observer at 30 m/s. The speed of sound in air is 340 m/s. Find the observed frequency.

Solution:

Using the Doppler shift formula for a moving source and stationary observer:

$$f_o = f_s \frac{v}{v - v_s}$$

$$f' = \frac{f}{1 - \frac{v_s}{v}}$$

\\

Where:

- f' = observed frequency
- f = emitted frequency = 500 Hz
- v_s = source velocity = 30 m/s (approaching, so positive)
- v = speed of sound = 340 m/s

Substituting:

\\

$$f' = \frac{500}{1 - \frac{30}{340}} = \frac{500}{1 - 0.0882} = \frac{500}{0.9118} \approx 548.4 \text{ Hz}$$

\\

Gizmo Answer: The observed frequency is approximately 548.4 Hz.

Problem 2: Observer Moving Away from a Stationary Source

Scenario: A stationary source emits at 600 Hz. The observer moves away at 20 m/s. Find the observed frequency.

Solution:

Using the formula for a moving observer:

\\

$$f' = f \times \left(\frac{v}{v + v_o} \right)$$

\\

Where:

- f' = observed frequency
- $f = 600$, Hz
- $v_o = 20$, m/s (away, so positive)
- $v = 340$, m/s

Calculating:

[

$$f' = 600 \times \left(\frac{340}{340 + 20} \right) = 600 \times \frac{340}{360} = 600 \times 0.9444 \approx 566.7, \text{Hz}$$

]

Gizmo Answer: The observed frequency is approximately 566.7 Hz.

Doppler Shift Advanced Gizmo Answers: A Comprehensive Guide to Understanding and Applying Doppler Effect Principles

The phenomenon of Doppler Shift Advanced Gizmo Answers offers a fascinating window into the complex behaviors of waves as they interact with moving sources and observers. Whether you're a student delving into physics, an educator designing experiments, or a science enthusiast eager to understand the nuances of wave behavior, mastering the advanced concepts behind the Doppler effect is essential. This guide aims to provide an in-depth exploration of the advanced gizmo answers related to Doppler shift, breaking down the core principles, common questions, and practical applications that illuminate the intricacies of this phenomenon.

Understanding the Basics of Doppler Shift

Before diving into the advanced aspects, it's crucial to establish a solid grasp of the fundamental principles.

What is the Doppler Effect?

The Doppler Effect describes the change in frequency or wavelength of a wave in relation to an observer moving relative to the wave source. Named after Christian Doppler, who proposed it in 1842, this effect manifests in various wave types—sound, light, and even electromagnetic waves.

Key points:

- When the source approaches the observer, the observed frequency increases.
- When the source recedes, the observed frequency decreases.
- The effect depends on the relative velocity between source and observer, not on their absolute motion.

Basic Doppler Shift Equation for Sound

For a stationary observer and a moving source:

$$f' = f \left(\frac{v}{v \pm v_s} \right)$$

Where:

- f' = observed frequency
- f = emitted frequency
- v = speed of sound in the medium
- v_s = speed of the source relative to the medium (positive when moving away)

Similarly, for a stationary source and a moving observer:

$$f' = f \left(\frac{v \pm v_o}{v} \right)$$

Where:

- v_o = observer's speed relative to the medium (positive when moving towards the source)

Advanced Gizmo Answers: Deep Dive into Complex Scenarios

The Doppler Shift Advanced Gizmo explores complex situations involving multiple variables: moving observers and sources, varying medium conditions, and electromagnetic waves. The answers provided by the gizmo are designed to challenge your understanding and develop problem-solving skills for real-world applications.

Common Advanced Questions Covered:

- How does the Doppler effect apply to light waves in astrophysics?
- What happens when both source and observer are moving?
- How do medium properties influence the observed shift?
- How is the Doppler effect used in technologies like radar and medical imaging?

Applying the Doppler Effect in Complex Situations

- Moving Source and Moving Observer

When both the source and observer are in motion, the observed frequency becomes:

$$f' = f \left(\frac{v + v_o}{v - v_s} \right)$$

Where:

- v_o = velocity of the observer towards the source
- v_s = velocity of the source away from the observer

Implications:

- If both move towards each other, the frequency increases more than in the case of a single moving object.
- If they move apart, the frequency decreases more significantly.

Example:

Suppose a train emitting sound at 500 Hz moves at 30 m/s away from a stationary observer. The observer then starts moving towards the train at 10 m/s. With the speed of sound at 340 m/s:

- Stationary observer:

$$f' = 500 \left(\frac{340}{340 + 30} \right) = 500 \left(\frac{340}{370} \right) = 500 \cdot 0.9189 = 459.45 \text{ Hz}$$

- Moving observer:

$$f' = 500 \left(\frac{340 + 10}{340 + 30} \right) = 500 \left(\frac{350}{370} \right) = 500 \cdot 0.9459 = 472.95 \text{ Hz}$$

This example illustrates how the observer's motion affects the perceived frequency, emphasizing the importance of considering both motions in advanced analyses.

- Doppler Effect in Electromagnetic Waves (Light)

Unlike sound, light waves do not require a medium and follow relativistic principles. The Doppler shift for light involves the relativistic Doppler formula:

$$f' = f \sqrt{\frac{1 + \beta}{1 - \beta}}$$

Where:

- $\beta = v / c$ (v = relative velocity, c = speed of light)

Key differences:

- No medium dependency.
- Significant at velocities close to the speed of light.
- Essential in astrophysics for understanding redshift and blueshift of celestial objects.

Advanced insight:

- Redshift indicates objects moving away.
- Blueshift indicates objects approaching.

Practical Applications and Implications of the Doppler Shift

- Radar and Speed Detection

Police radar guns utilize the Doppler effect to measure vehicle speeds. The emitted microwave signal reflects off moving vehicles, and the frequency shift correlates directly with speed.

Key points:

- The greater the frequency shift, the higher the speed.
- Advanced gizmo answers help interpret readings under various conditions, such as multiple moving targets or obstructions.

- Medical Imaging: Doppler Ultrasound

Doppler ultrasound detects blood flow and heart movements by measuring frequency shifts in reflected sound waves. Understanding advanced concepts allows clinicians to accurately interpret flow direction and velocity, crucial in diagnosing vascular conditions.

- Astronomical Observations

Redshift and blueshift are vital for studying the universe:

- Measuring galaxy velocities moving away (redshift) supports the expanding universe model.
- Precise calculations require understanding relativistic Doppler formulas.

Troubleshooting and Common Challenges in Advanced Doppler Applications

- Accounting for medium variations: Temperature, humidity, and pressure can influence wave

speed, affecting calculations.

- Dealing with multiple sources or reflections: Complex environments may produce overlapping signals, requiring advanced analysis techniques.

Waves Ch 11 2 Answers

waves ch 11 2 answers is a common query among students studying physics, particularly those focusing on the chapter related to waves. Understanding the key concepts in Chapter 11, Section 2, is crucial for mastering the topic of wave behavior, properties, and the fundamental principles that govern wave motion. In this comprehensive article, we will explore the essential answers and explanations related to waves in Chapter 11, Section 2, providing clarity and insight to help students excel in their studies.

Understanding Waves: An Overview

Before diving into specific questions and answers, it is important to establish a foundational understanding of what waves are and their significance in physics.

What Are Waves?

Waves are disturbances that transfer energy from one point to another without the transfer of matter. They are characterized by oscillations or vibrations that propagate through a medium or even through space in the case of electromagnetic waves.

Types of Waves

Waves can be broadly categorized into:

- **Mechanical Waves:** Require a medium to travel through, such as sound waves, water waves, and seismic waves.
- **Electromagnetic Waves:** Do not need a medium and can travel through a vacuum, including light, radio waves, and X-rays.

Key Concepts in Chapter 11, Section 2

This section typically covers the properties and behaviors of waves, including wave speed, frequency, wavelength, and the types of wave interactions. The following subsections address common questions and their answers.

Q1: What is the relationship between wave speed, wavelength, and frequency?

A fundamental concept in wave physics is the wave equation:

- **Wave Speed (v):** The speed at which a wave propagates through a medium.
- **Wavelength (λ):** The distance between two consecutive points in phase on the wave, such as crest to crest.
- **Frequency (f):** How many waves pass a fixed point per second.

The relationship is given by:

$$v = \lambda \times f$$

This means that if the wavelength increases while the wave speed remains constant, the frequency decreases, and vice versa.

Q2: How does wave reflection occur, and what are its types?

Wave reflection occurs when a wave encounters a boundary and bounces back into the original medium. Key types include:

- **Specular Reflection:** Reflection from smooth surfaces, like a mirror, which produces a clear image.

- **Diffuse Reflection:** Reflection from rough surfaces, scattering waves in many directions.

In the context of Chapter 11, Section 2, understanding how waves reflect helps explain phenomena such as echoes and the behavior of waves at boundaries.

Q3: What is the principle of superposition, and how does it relate to wave interference?

The principle of superposition states that when two or more waves overlap, the resulting displacement is the algebraic sum of the individual displacements. This principle explains interference patterns:

- **Constructive Interference:** When waves are in phase, their amplitudes add, resulting in a larger wave.
- **Destructive Interference:** When waves are out of phase, their amplitudes subtract, possibly canceling each other out.

Superposition is fundamental to phenomena like standing waves and diffraction.

Common Questions and Their Detailed Answers

Below are elaborated answers to typical questions students encounter regarding Chapter 11, Section 2.

Q4: How do standing waves form, and what are their characteristics?

Standing waves form when two waves of equal frequency, amplitude, and speed travel in opposite directions and interfere. They are characterized by:

- **Nodes:** Points of zero displacement where destructive interference occurs.
- **Antinodes:** Points of maximum displacement resulting from constructive interference.

Standing waves are common in musical instruments and transmission lines, illustrating resonance phenomena.

Q5: What factors affect wave speed in a medium?

Several factors influence the speed at which waves travel:

- **Type of Medium:** Different materials have different properties; for example, sound travels faster in steel than in air.
- **Elasticity:** More elastic materials allow waves to propagate faster.
- **Density:** Generally, denser media slow down wave propagation, but elasticity can counteract this effect.
- **Temperature:** Increased temperature can increase wave speed, especially in gases.

Understanding these factors helps explain variations in wave behavior across different environments.

Q6: How does the Doppler Effect influence wave observations?

The Doppler Effect describes the change in frequency or wavelength of a wave as the source and observer move relative to each other:

- Approaching source: The observed frequency increases (higher pitch in sound).
- Receding source: The observed frequency decreases (lower pitch).

This effect is crucial in applications like radar, astronomy, and medical imaging.

This comprehensive review aims to delve into the core ideas, solution strategies, and key concepts associated with Waves Chapter 11.2, particularly focusing on the answers and explanations typical of textbook exercises.

Introduction to Wave Fundamentals

Before diving into specific problem solutions, it's essential to revisit the fundamental principles of waves. These concepts form the backbone of Chapter 11.2 and are crucial for understanding the detailed answers.

Types of Waves

Waves are generally classified into two main categories:

- Mechanical Waves: Require a medium (solid, liquid, or gas) to travel through. Examples include sound waves, water waves, and seismic waves.
- Electromagnetic Waves: Do not need a medium; they travel through a vacuum. Examples include light, X-rays, and radio waves.

Wave Properties

Key properties of waves include:

- Wavelength (λ): The distance between successive crests or troughs.
- Frequency (f): How many waves pass a point per second.
- Period (T): The time it takes for one complete wave cycle ($T = 1/f$).
- Wave Speed (v): How fast the wave propagates through the medium, calculated as $v = f\lambda$.
- Amplitude: The maximum displacement from the rest position, related to wave energy.
- Phase: The position of a point within the wave cycle.

Core Concepts in Chapter 11.2

Chapter 11.2 often emphasizes specific phenomena, such as wave interference, standing waves, wave reflection and transmission, Doppler effect, and energy transfer.

Wave Interference

- Constructive Interference: When wave crests align, resulting in increased amplitude.
- Destructive Interference: When crest aligns with troughs, reducing overall amplitude.
- Principle of Superposition: The net displacement is the algebraic sum of individual wave displacements.

Standing Waves and Resonance

- Standing Waves: Result from the interference of two waves traveling in opposite directions with the same frequency and amplitude, producing nodes (points of zero displacement) and antinodes (points of maximum displacement).
- Resonance: When a system is driven at its natural frequency, leading to large amplitude oscillations. Analyzing resonance involves understanding boundary conditions and harmonic modes.

Reflection and Transmission of Waves

- When waves encounter a boundary between two media, part of the wave is reflected, and part is transmitted.
- The reflection coefficient depends on the impedance mismatch between media.
- Reflection can invert the wave depending on boundary conditions (fixed or free).

Doppler Effect

- Describes the change in observed frequency when the source or observer moves relative to each other.
- The formula for observed frequency:

$\backslash$

$$f' = \frac{f(v \pm v_o)}{v \mp v_s}$$

$\backslash$

where $\backslash(v)$ is wave speed, $\backslash(v_o)$ is observer velocity, and $\backslash(v_s)$ is source velocity.

Analyzing Typical Chapter 11.2 Problems and Answers

The answers in Chapter 11.2 exercises serve as a guide for students to understand how to approach complex wave problems systematically. Here, we analyze common problem types and the reasoning behind their solutions.

Problem Type 1: Calculating Wave Speed

Sample Question:

A wave on a string has a wavelength of 0.5 m and a frequency of 4 Hz. What is the wave speed?

Answer Approach:

- Recall the fundamental wave relation:

$$v = f \lambda$$

$$v = f \lambda$$

$$v = 4 \text{ Hz} \times 0.5 \text{ m} = 2 \text{ m/s}$$

- Substitute the known values:

$$v = 4 \text{ Hz} \times 0.5 \text{ m} = 2 \text{ m/s}$$

$$v = 4 \text{ Hz} \times 0.5 \text{ m} = 2 \text{ m/s}$$

$$v = 4 \text{ Hz} \times 0.5 \text{ m} = 2 \text{ m/s}$$

Key Takeaway:

Ensure units are consistent; the problem's simplicity emphasizes the importance of understanding the relation between frequency, wavelength, and speed.

Problem Type 2: Interference and Superposition

Sample Question:

Two waves of equal amplitude and frequency interfere constructively at a point. If each wave has an amplitude of 3 cm, what is the resultant amplitude?

Answer Approach:

- For constructive interference with two waves of equal amplitude:

$$A_{\text{resultant}} = A_1 + A_2 = 3\text{ cm} + 3\text{ cm} = 6\text{ cm}$$

- When multiple waves interfere, the principle of superposition applies, and amplitudes add algebraically for constructive interference.

Important Note:

In cases involving multiple waves or varying phases, more advanced vector addition or phasor methods may be necessary.

Problem Type 3: Standing Wave Frequencies and Modes

Sample Question:

A string fixed at both ends has a length of 2 m. What are the frequencies of the first and second harmonics if the wave speed is 4 m/s?

Answer Approach:

- For a string fixed at both ends, the harmonics are given by:

$$f_n = n \frac{v}{2L}$$

where $(n = 1, 2, 3, \dots)$

- Calculate the fundamental frequency ($n=1$):

$$f_1 = 1 \times \frac{4 \text{ m/s}}{2 \times 2 \text{ m}} = 1 \text{ Hz}$$

- Second harmonic ($n=2$):

$$f_2 = 2 \times \frac{4 \text{ m/s}}{2 \times 2 \text{ m}} = 2 \text{ Hz}$$

Implication:

Understanding harmonic modes is crucial for analyzing musical instruments, waveguides, and structural vibrations.

Common Challenges and Clarifications in Chapter 11.2 Answers

Many students encounter difficulties interpreting or applying wave concepts. Here, we address some common misconceptions and clarify solution strategies.

Misconception 1: Confusing Wave Speed with Frequency or Wavelength

- Clarification:

Wave speed is independent of frequency and wavelength; rather, it depends on the medium. The relation $v = f \lambda$ links these quantities, but knowing any two allows calculation of the third.

Misconception 2: Assuming All Waves Interfere Constructively or Destructively

- Clarification:

Interference depends on phase differences. Not all superpositions are purely constructive or

destructive; often, partial interference occurs, requiring phase analysis.

Misconception 3: Overlooking Boundary Conditions in Standing Waves

- Clarification:

Nodes and antinodes are determined by boundary conditions. Fixed ends always correspond to nodes; free ends can correspond to antinodes. Correctly applying boundary conditions is essential for accurate harmonic calculations.

Issue: Applying the Correct Sign in Doppler Effect Calculations

- Solution:

Always carefully analyze the relative motion directions. Conventionally, if the source approaches the observer, the observed frequency increases; if receding, it decreases. Sign conventions in formulas must be applied consistently.

Real-World Applications and Relevance of Chapter 11.2 Concepts

Understanding wave answers extends beyond theoretical exercises. Real-world phenomena rely on these principles:

- Music and Acoustics:

Harmonics and standing waves determine instrument sounds.

- Communication Technologies:

Radio wave transmission involves interference, reflection, and Doppler shifts.

- Seismology:

Wave reflection and transmission help locate earthquakes.

- Medical Imaging:

Ultrasound waves utilize wave reflection and interference.

- Engineering:

Designing structures to avoid destructive resonance or to harness standing waves.

Strategies for Mastering Chapter 11.2 Problems

To excel in solving wave problems and understanding their answers, students should adopt systematic approaches:

- Identify the Type of Wave Phenomenon:

- Interpret the Results Physically:

Ensure answers make sense in context. For example, wave speeds should be

Question What are the main topics covered in Chapter 11.2 of Waves? Chapter 11.2 focuses on the properties of wave speed, types of waves (transverse and longitudinal), and how waves transfer energy without transferring matter. How is wave speed calculated in Chapter 11.2? Wave speed is calculated using the formula $v = f\lambda$, where v is wave speed, f is frequency, and λ is wavelength. What is the difference between transverse and longitudinal waves as explained in Chapter 11.2? Transverse waves move particles perpendicular to the direction of wave travel, while longitudinal waves move particles parallel to the wave's direction of travel. Why do different types of waves travel at different speeds according to Chapter 11.2? Different waves travel at different speeds because of the medium's properties, such as density and elasticity, which affect how quickly energy propagates through the medium. How does Chapter 11.2 explain the relationship between frequency and wavelength? Chapter 11.2 explains that frequency and wavelength are inversely related; as frequency increases, wavelength decreases, assuming wave speed remains constant. What are real-life examples of waves discussed in Chapter 11.2? Examples include sound waves, light waves, and water waves, illustrating how waves transfer energy across different mediums in everyday life.

- Restating the problem with known variables.
- Applying relevant formulas, such as:

$$f' = \frac{v \pm v_o}{v \mp v_s} \times f$$

$$f' = \frac{v \pm v_o}{v \mp v_s} \times f$$

where:

- f' = observed frequency
- v = wave speed in medium
- v_o = observer velocity
- v_s = source velocity
- f = emitted frequency

- Explaining why certain signs are used depending on whether the source or observer moves towards or away.

- Calculating intermediate values, like wavelength or relative velocities, to reinforce understanding.

- Confirming the final result with units and logical consistency.

This approach helps users see not just the answer but the reasoning behind it.

2. Variations for Different Scenarios

Sample Problems and Their Solutions

To illustrate the depth of the answers key, here are summarized examples.

Example 1: Moving Source Approaching Stationary Observer

Problem: A police car emits a siren at a frequency of 1000 Hz. The car approaches a stationary observer at 30 m/s, while the speed of sound in air is 340 m/s. What is the perceived frequency?

Solution:

- Known:
 - $f = 1000 \, \text{Hz}$
 - $v = 340 \, \text{m/s}$
 - $v_s = 30 \, \text{m/s}$ (approaching, so positive in the formula)
 - $v_o = 0 \, \text{m/s}$
- Using the Doppler formula for a moving source approaching stationary observer:

$$f' = \frac{v}{v - v_s} \times f$$

$$f' = \frac{340}{340 - 30} \times 1000$$

$$f' = \frac{340}{310} \times 1000 \approx 1.0968 \times 1000 \approx 1096.8 \, \text{Hz}$$

- Calculation:

$$f' = \frac{340}{340 - 30} \times 1000 = \frac{340}{310} \times 1000 \approx 1.0968 \times 1000 \approx 1096.8 \, \text{Hz}$$

$$f' = \frac{340}{340 - 30} \times 1000 = \frac{340}{310} \times 1000 \approx 1.0968 \times 1000 \approx 1096.8 \, \text{Hz}$$

\]

- Answer: The observer perceives approximately 1097 Hz.

The answers key would explain each step, emphasizing sign conventions and formula application.

Example 2: Moving Observer Receding from Stationary Source

Problem: A stationary source emits sound at 800 Hz. An observer moves away at 15 m/s. The speed of sound is 340 m/s. Find the perceived frequency.

Solution:

- Known:
- $f = 800 \text{ Hz}$
- $v = 340 \text{ m/s}$
- $v_o = 15 \text{ m/s}$ (receding, so subtract in the denominator)
- $v_s = 0 \text{ m/s}$

- Using the formula for a moving observer:

\[

$$f' = \left(\frac{v - v_o}{v} \right) \times f$$

\]

- Calculation:

\[

$$f' = \left(\frac{340 - 15}{340} \right) \times 800 = \left(\frac{325}{340} \right) \times 800 \approx 0.9559 \times 800 \approx 764.7 \text{ Hz}$$

\]

- Answer: The observer perceives approximately 765 Hz.

The key would include notes on the importance of sign conventions and the impact of the observer moving away.
